Notes

HTML - Basics

Concepts

HTML (HyperText Markup Language) is the **foundation of every webpage**. It is used to define the **structure and layout** of content like text, images, links, and more.

Instead of programming logic, HTML uses **tags** to describe elements. These tags tell the browser **what to display and how content is organized**.

Example:

- Headings
- Paragraphs

- Images
- Links

◆ Types of Tags

HTML tags are categorized based on how they behave:

1. Normal (Paired Tags)

These tags have both **opening and closing parts**.

👉 Example:

```
<p>This is a paragraph</p>
```

2. Self-Closing Tags

These tags **don't need a closing tag** because they don't wrap content.

👉 Example:

```
<br>  
<imgsrc="image.jpg">  
<hr>
```

3. Block-Level Tags

- Take **full width** of the page
- Always start on a **new line**

👉 Example:

```
<div>Block Element</div>  
<p>Paragraph</p>
```

4. Inline Tags

- Take only **required space**
- Stay in the **same line**

👉 Example:

```
<span>Inline Text</span>  
<a href="#">Link</a>
```

5. Semantic Tags

These tags give **meaning** to content, improving SEO and readability.

👉 Example:

```
<header></header>  
<footer></footer>  
<article></article>
```

Structure Tags

These tags define the **basic skeleton of a webpage**:

- `html` → Root element (everything is inside this)
- `head` → Contains metadata (not visible to users)
- `title` → Page title (browser tab name)
- `body` → All visible content

👉 Additional:

- `meta` → SEO / charset info
- `link` → Connect external CSS
- `style` → Internal CSS
- `script` → JavaScript

Text & Content Tags

Used to display **basic readable content**:

- `h1` to `h6` → Headings (h1 = most important)
- `p` → Paragraph text
- `br` → Line break
- `hr` → Horizontal divider

👉 These tags help structure content for users and search engines.

Formatting Tags

Used to **style or emphasize text**:

- `b` → Bold (visual only)
- `strong` → Important (semantic bold)
- `i` → Italic
- `em` → Emphasized (semantic italic)
- `u` → Underline
- `mark` → Highlight
- `small` → Smaller text
- `del` → Deleted (strike-through)
- `sub` → Subscript (H₂O)
- `sup` → Superscript (x²)

👉 Difference:

- `b` vs `strong` → strong has meaning
 - `i` vs `em` → em has importance
-

Links & Navigation

♦ Anchor Tag (`a`)

Used to create **clickable links**.

👉 Example:

```
<ahref="https://google.com">Visit Google</a>
```

Other uses:

- WhatsApp → `https://wa.me/number`
- Email → `mailto:example@gmail.com`
- SMS → `sms:+91...`

Media Tags

Used to add **multimedia content**:

- `img` → Displays images (`src` , `alt`)
- `audio` → Adds audio
- `video` → Adds video
- `iframe` → Embeds external content (YouTube, maps)

👉 Important:

Always use `alt` in images for accessibility + SEO.

Lists

Used to organize content in **list format**:

- `ul` → Unordered list (bullets)
- `ol` → Ordered list (numbers)
- `li` → List items

👉 Example:

```
<ul>
<li>HTML</li>
<li>CSS</li>
</ul>
```

Summary

- HTML defines the **structure of a webpage**
- Tags are used to create and organize content
- Semantic tags improve **SEO and readability**
- Clean structure helps in **scalability and maintenance**

Best Practices

- Use semantic tags wherever possible
- Maintain heading hierarchy (`h1` → `h6`)
- Always add `alt` in images
- Avoid unnecessary tags
- Keep code clean and readable

Pro Tip

Clean HTML structure = Better SEO + Better readability + Easier development
